

Catchment Area Delineation Using GIS technique for Bekhma Dam

Mudher N. Abdullah
MOWR Iraq

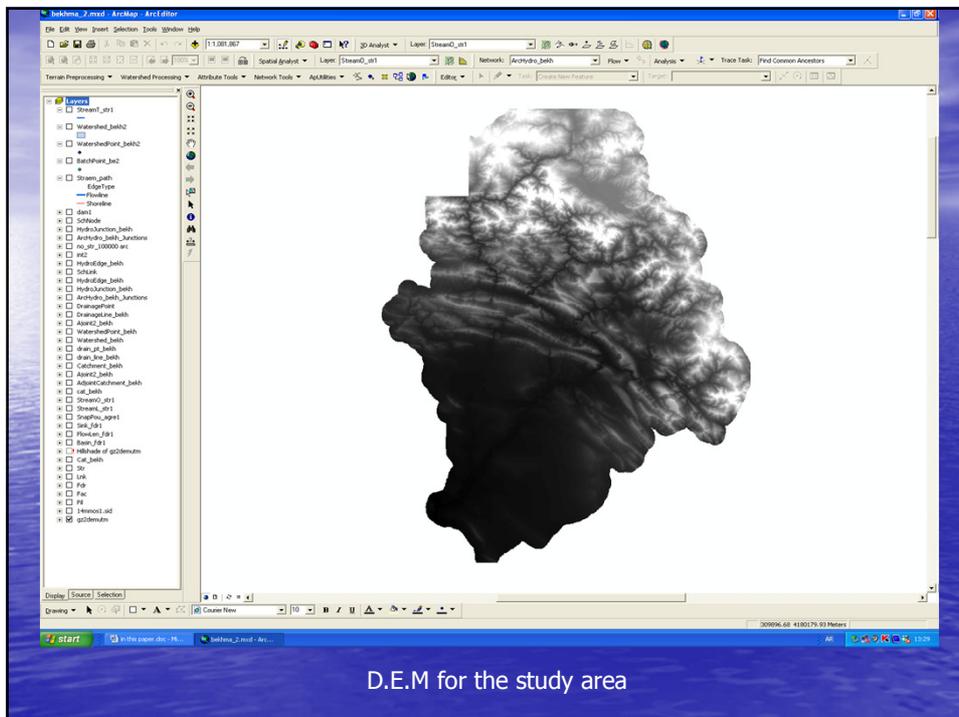

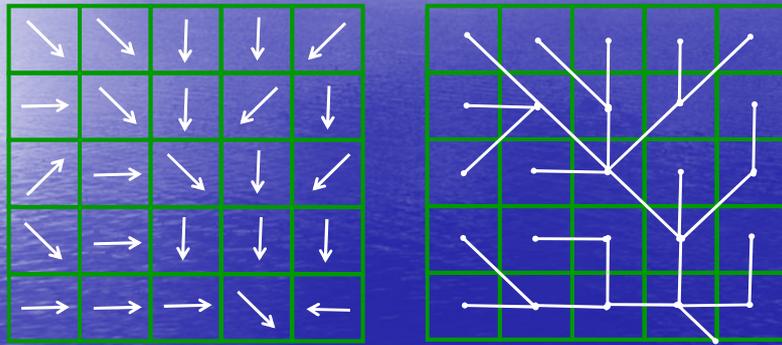

This paper represents a methodology
for DEM pre-processing that
provides the basis for fast and
consistent watershed delineation
on DEMs of any resolution and size
using desktop GIS technology

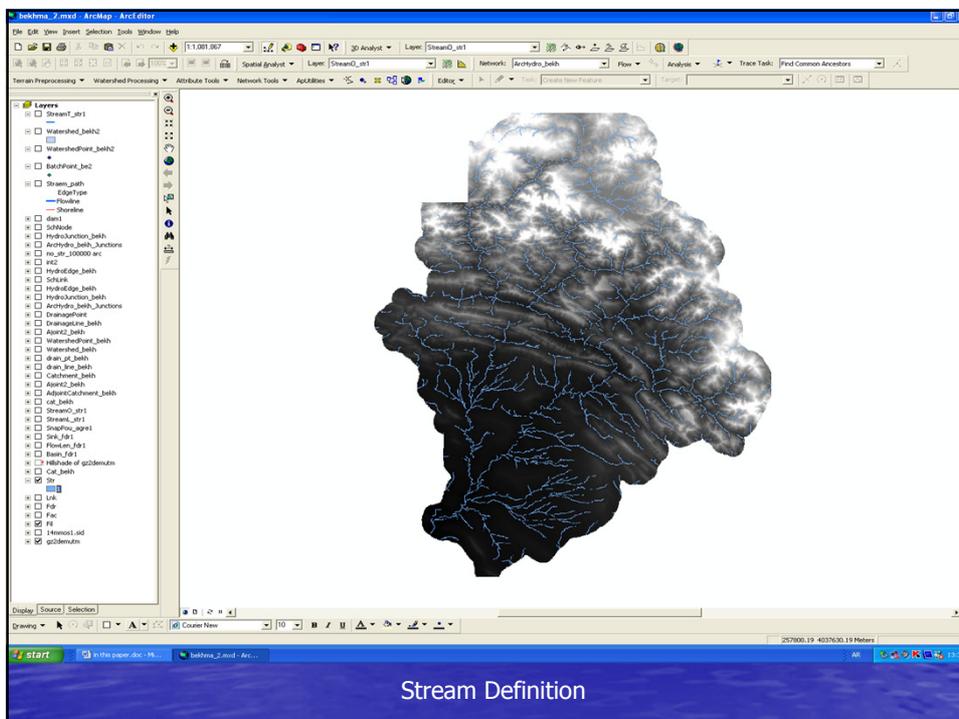

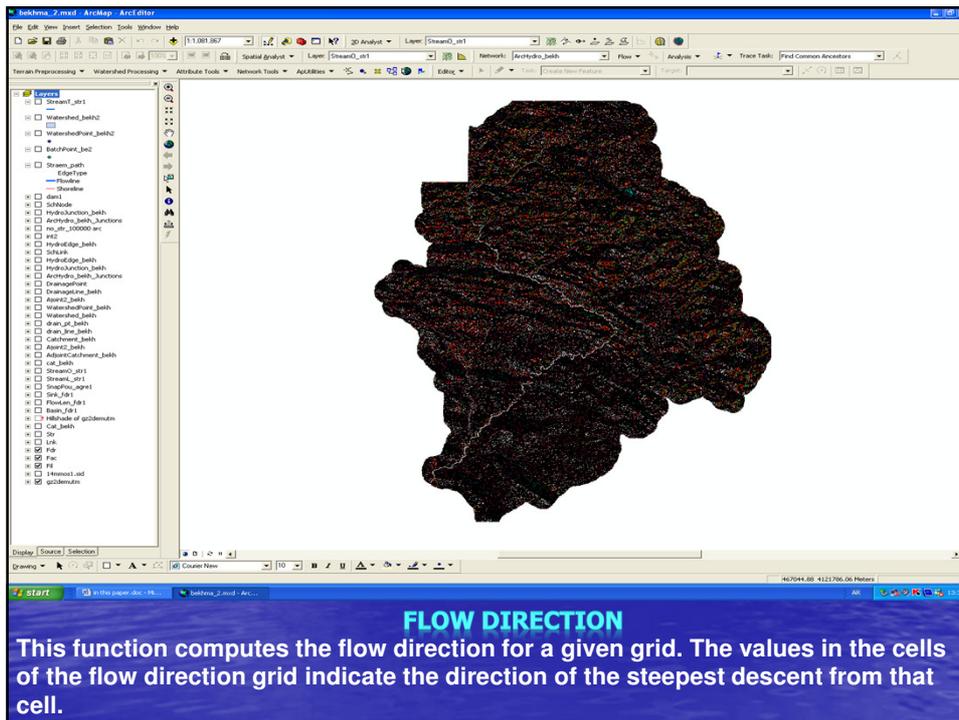

- ❖ The main data is the DEM with 1 arc second to get as much accurate results as could.
- ❖ Raster analysis is performed to generate data on flow direction, flow accumulation, stream definition, stream segmentation, and watershed delineation.
- ❖ The utility of Arc Hydro tools (GIS) is used to develop attributes that can be useful in hydrologic modeling.
- ❖ Watershed delineation is one of the most commonly performed activities in hydrologic analyses.
- ❖ Digital elevation models (DEMs) provide good terrain representation from which watersheds can be derived automatically using GIS technology.

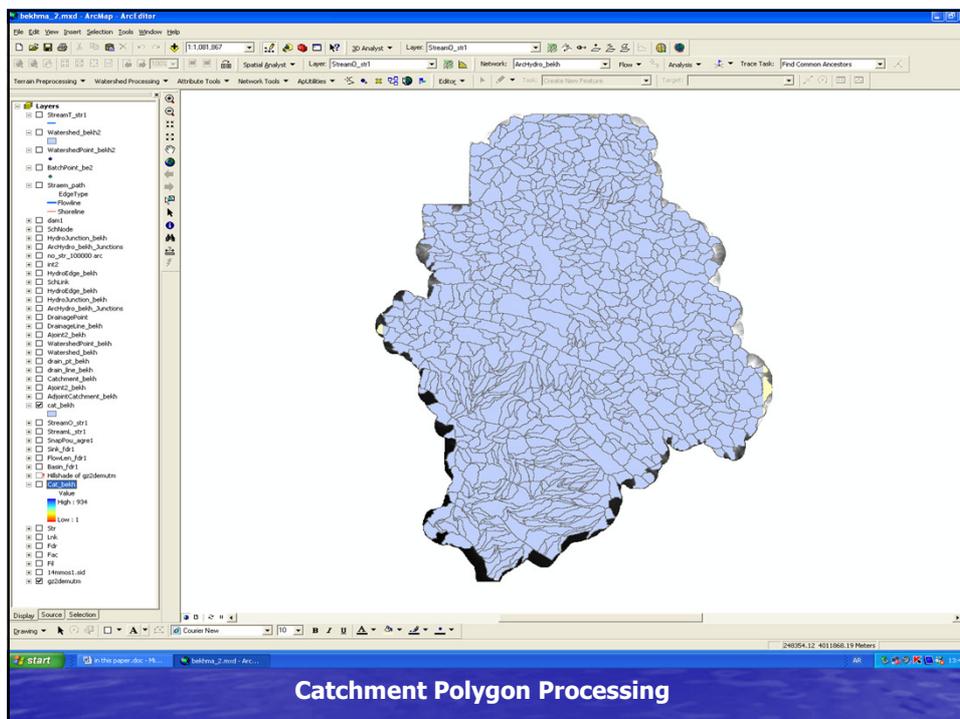

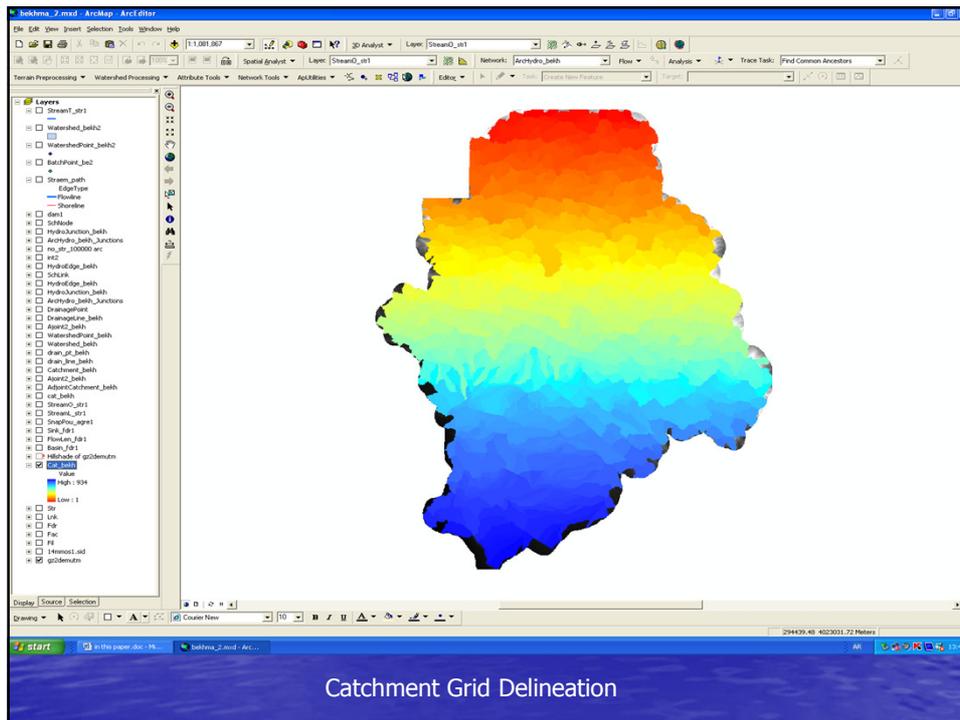

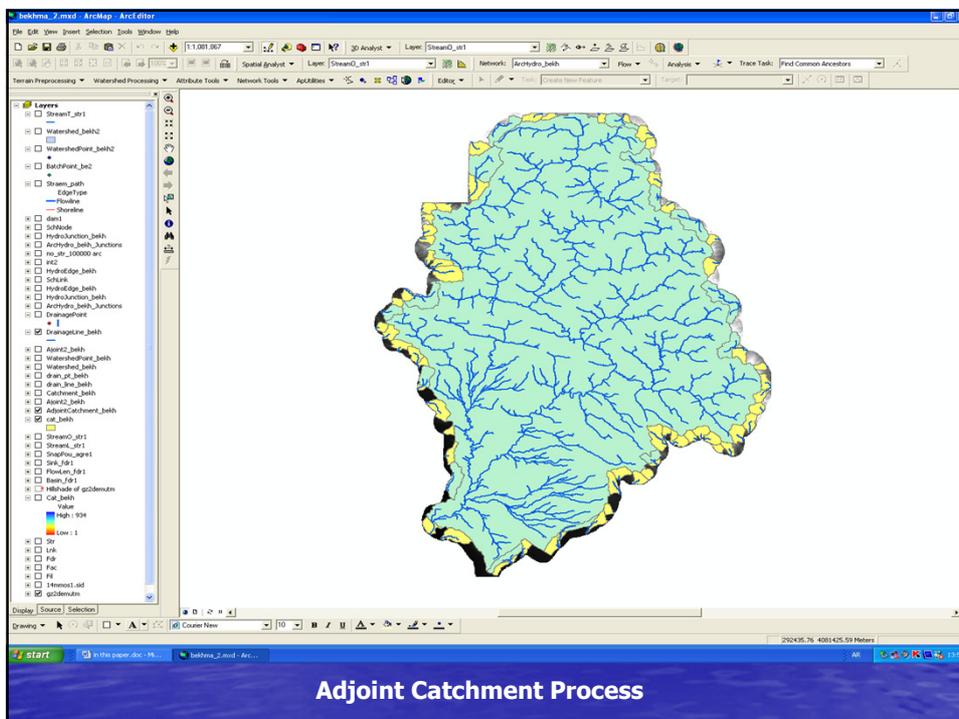

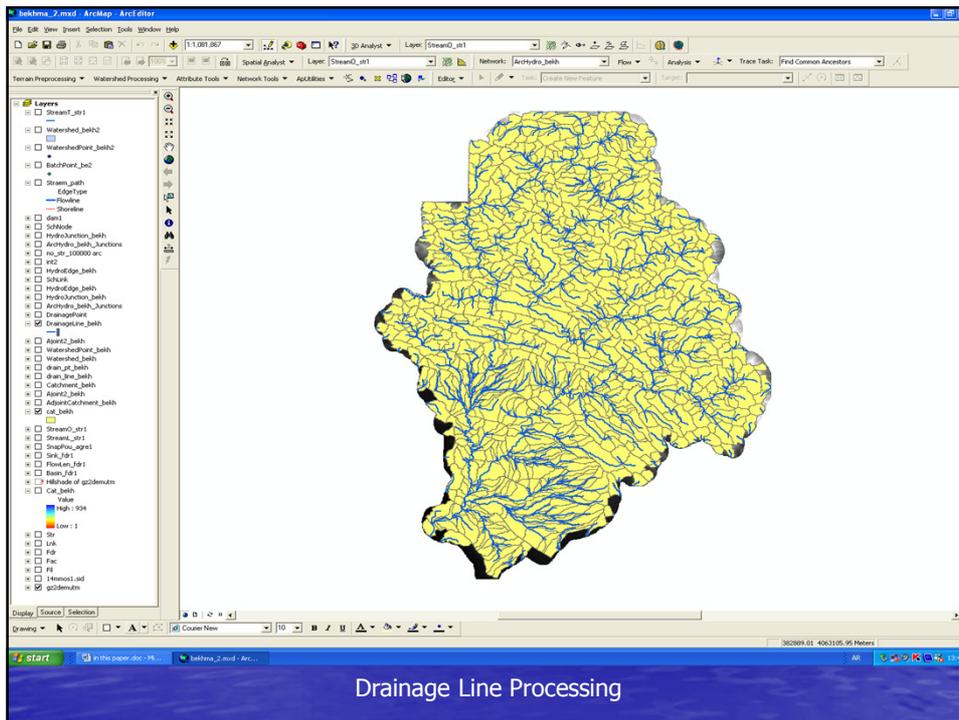

Grid Network

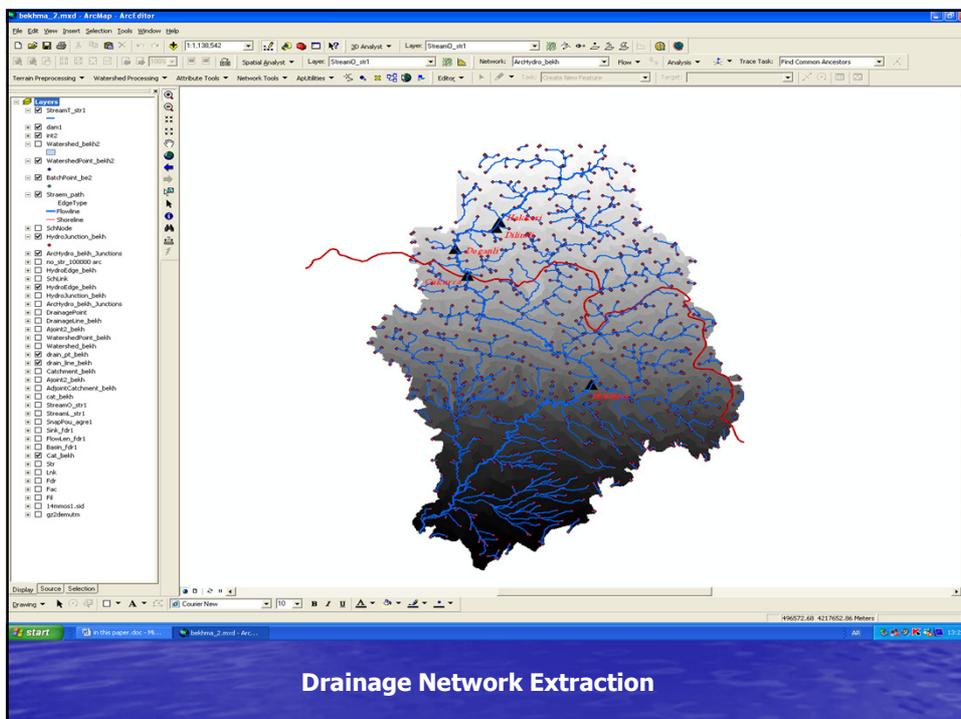

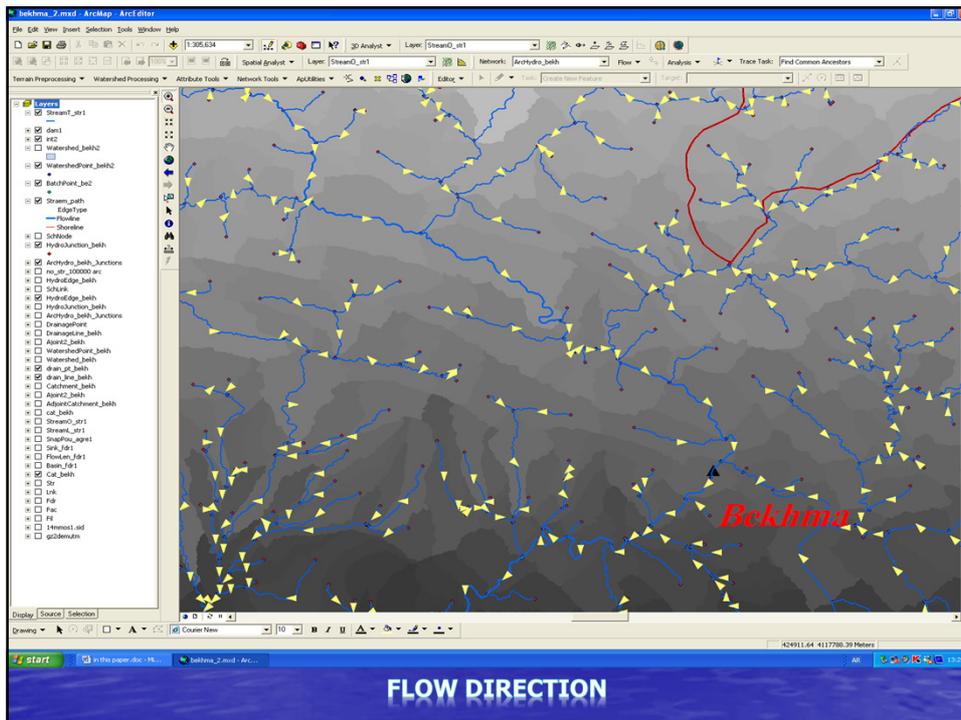

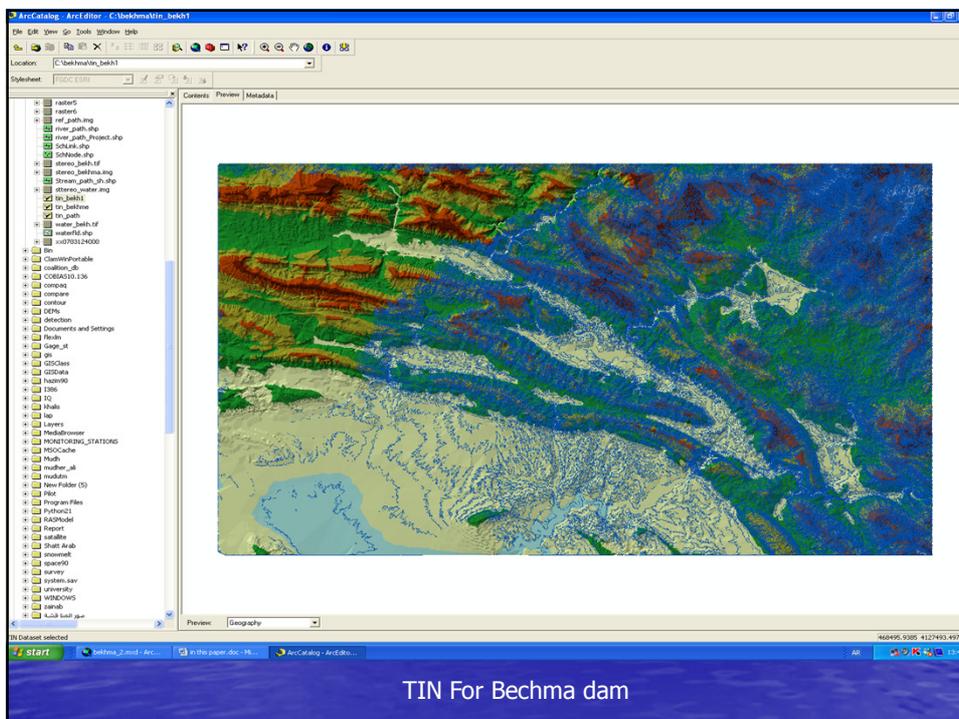

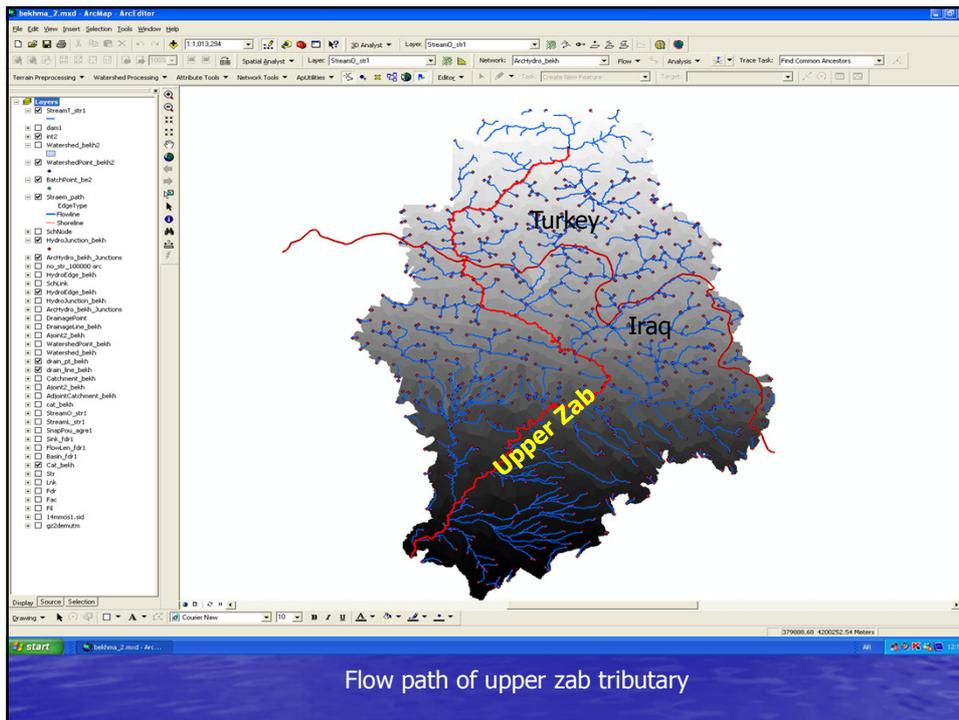

D.E.M for the study area

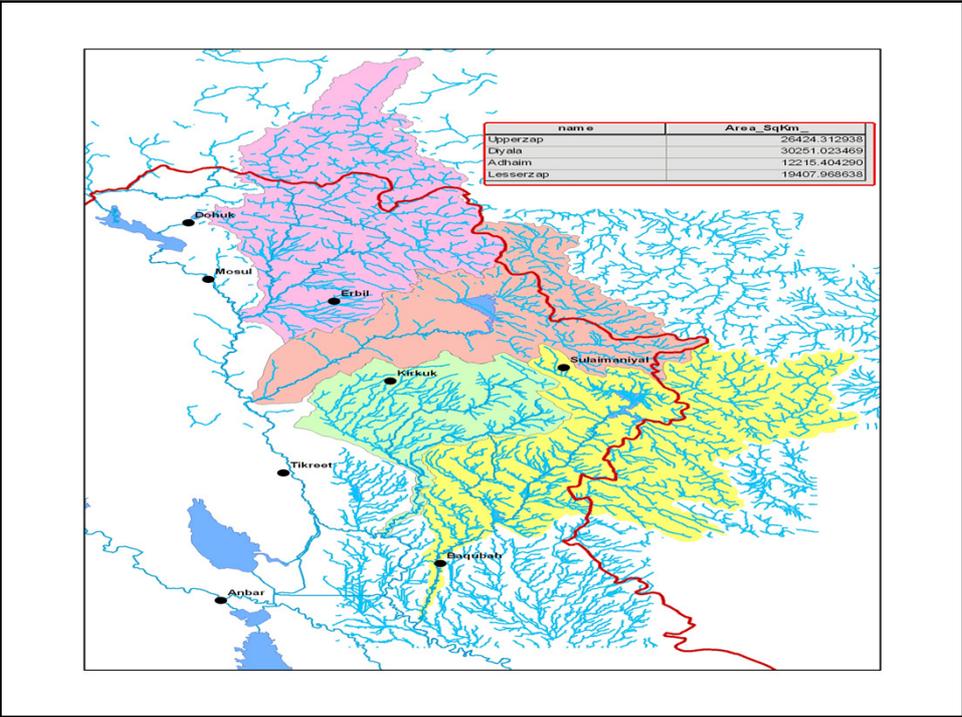

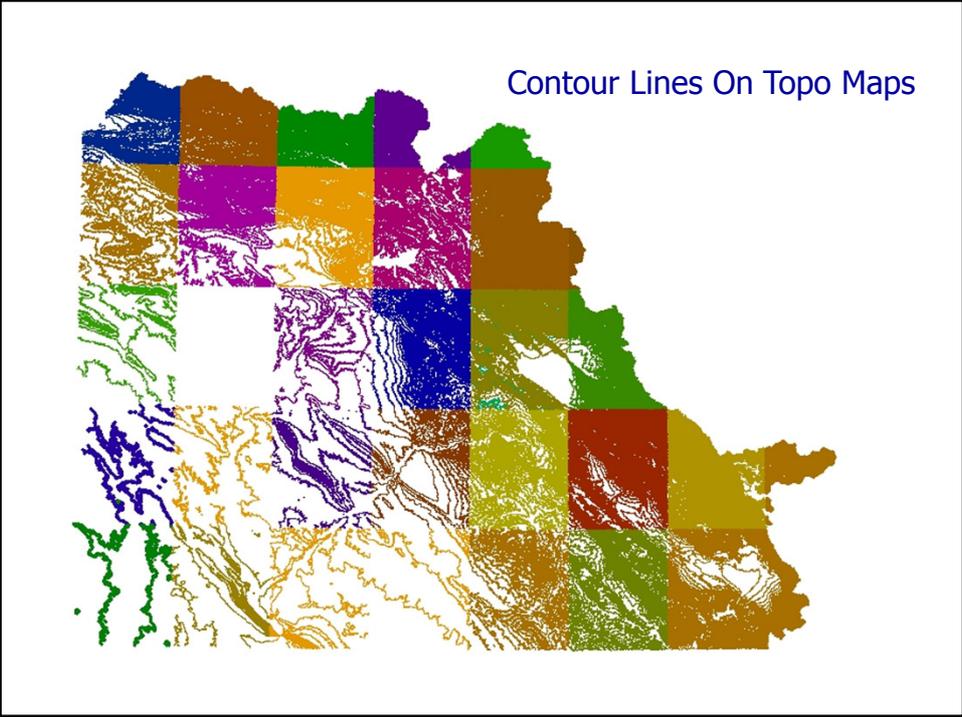

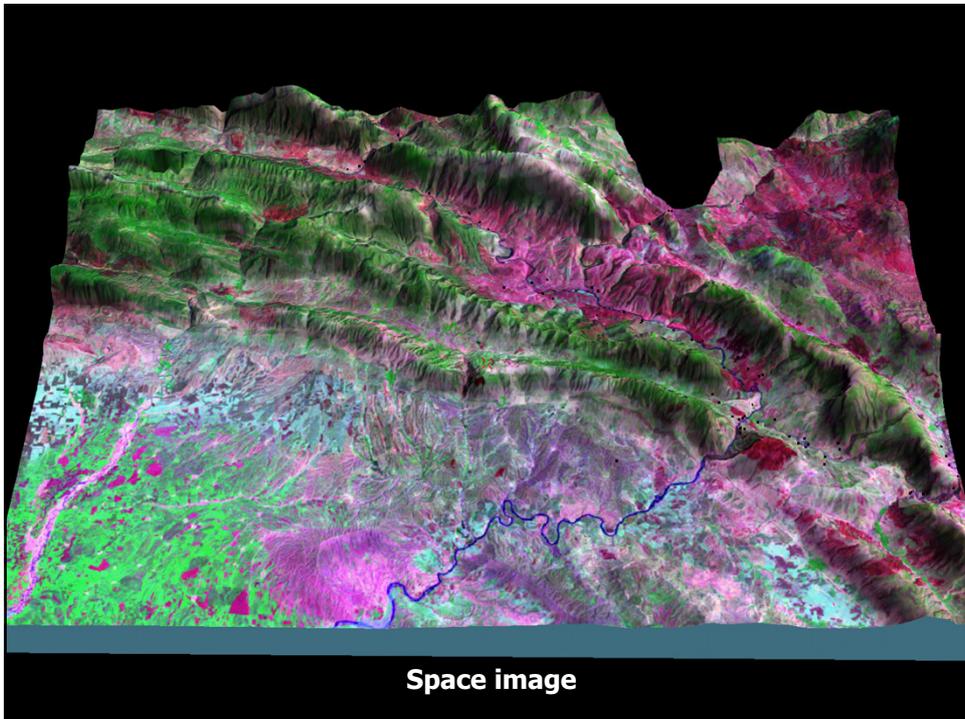

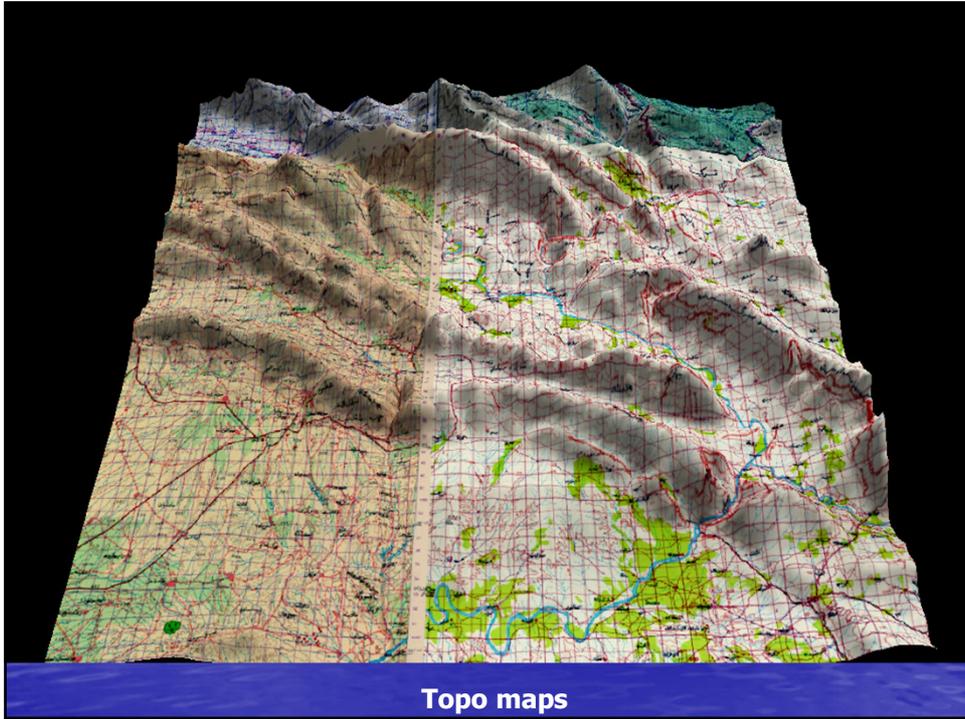

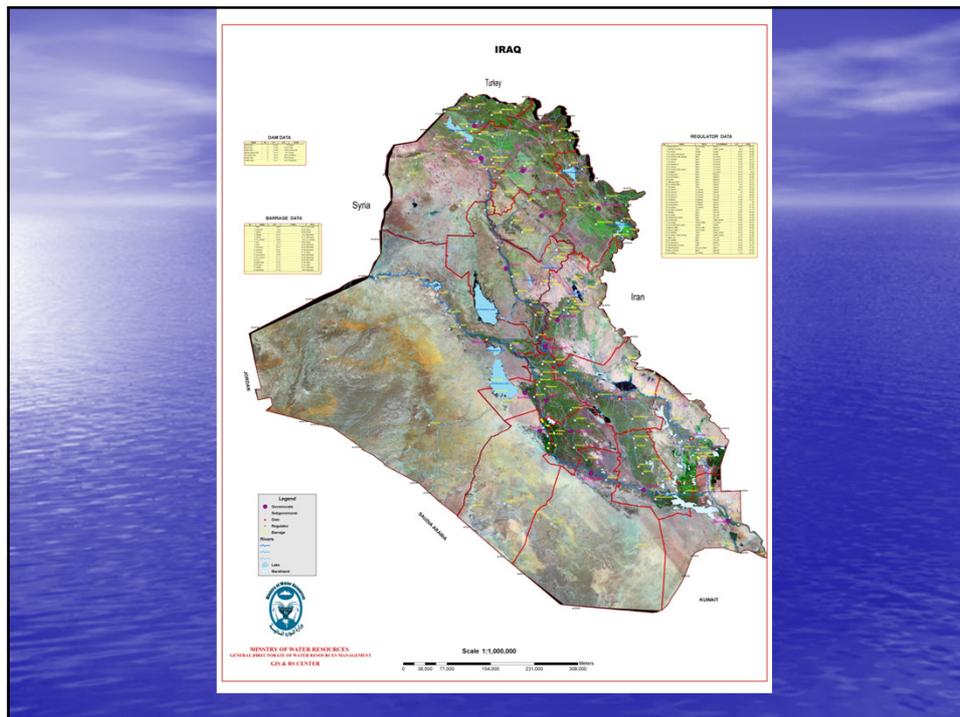

Conclusion

1. We find the great importance of using the D.E.M. in hydrographic studies.
2. Instead of studying the contour lines for many topographic maps which take long time to understand the topo surface, then delineated the watershed of each stream or river, we used here the ArcHydro extension that use the D.E.M. as a base for analyze and delineate the watershed in few hours and find it's area directly.
3. One of the great advantages of using GIS for hydrologic studies is to suggest the best location for dams or to locate monitoring (gauge) points.
